PHP BTECH BATCH 4, Day - 7

Request Method:

As programmers, there might be a chance where it is unclear which Request Method is used, in such scenario, we use the REQUEST METHOD key by $_SERVER

```
if($_SERVER["REQUEST_METHOD"]=="POST"){
    .... = $_POST[....]
}
else{
    .... = $_GET[....]
}
```

key containing information on the type of request method used

Using name as array

It becomes to keep track of names used in input fields, as our website scales. As such, it is necessary to use names as arrays so that we can fetch data with the same name.

```
<form action="valid.php" method="get">

    <label for="number1">Enter A Number: </label>
    <input type="number" name="number[]" id="number1">

    <label for="number2">Enter A Number: </label>
    <input type="number" name="number[]" id="number2">

    <label for="number3">Enter A Number: </label>
    <input type="number" name="number[]" id="number3">

</form>
```

here, we are using the word number[] multiple times the symbol [] specifies the server to treat it as an array, and NOT OVERWRITE previous values given to it.
